

QUICK REFERENCE GUIDE: RABIES

Rabies is a **FATAL** disease of the brain of mammals caused by infection with a virus. It is widespread in NY. Rabies vector species are animals with a high rate of infection such as **raccoons, skunks, and bats**. Rabies does not infect birds or reptiles.

An exposed animal may incubate the virus for several months before becoming ill. **SIGNS** can include weakness, paralysis, incoordination, aggression, or a "tame" appearance.

Because the **signs are so variable**, rabies can't be diagnosed or ruled out just by looking at an animal. In some species like fox and raccoon, **rabies and distemper can look identical**. Once signs appear, rabies is almost universally fatal.

TRANSMISSION occurs when saliva, brain tissue, or fluid from the central nervous system of an infected animal contacts a wound, eyes or mouth. This is typically via a **bite, scratch, or splash of fluids**. Frozen carcasses could still be infectious after months.

Rabies can only be diagnosed with a laboratory test of a brain sample. When euthanizing an animal that needs testing, it's important to **avoid damaging the brain and to limit contact with fluids**.

In NY only the **Department of Health** determines if contact with an animal is a **rabies exposure risk** for humans or domestic pets.

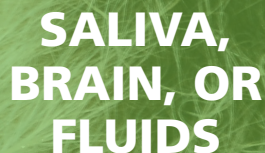

When there are any **concerns about human or pet interaction** with wildlife, NYSDEC personnel should **first contact** the local **County Health Department** Rabies Coordinator so they can determine if any exposure occurred. They will coordinate testing and treatment. Make sure to **COLLECT** name, address, and telephone number of any exposed persons for NYSDOH.

For additional support or to submit cases with no human or domestic animal exposure, contact the **Wildlife Health Program**; Delmar (518-478-3034) or Cornell (607-253-3134).
