The New York State Cooperative Wildlife Health Program (WHP) is a partnership between the NYSDEC Bureau of Wildlife and Cornell University's College of Veterinary Medicine AHDC that works to safeguard the long-term health of the wildlife populations of New York.

**CAUSES OF DEATH**

- **Bacterial**
- **Fungal**
- **Nutritional**
- **Parasitic**
- **Pending**
- **Poisoning**
- **Toxin**
- **Trauma**
- **Undetermined**
- **Unknown**
- **Viral**

**Rabies tests**
- **5 Positive**
- **83 Total**

**targeted Health Surveillance**

- **CWD**
- **Distemper**
- **Rabies**
- **Rodenticide Poisoning**
- **West Nile Virus**

**Total submissions**
- **286**

**Submissions by Region**

- **Mammals**
- **Birds**
- **Herpetofauna**

**23** Bald eagle submissions
- **14** with trauma as cause of death

**30** Bird species
- **116** submissions

**3** Herp species
- **9** submissions

**19** Mammal species
- **149** submissions

**New York State Wildlife Health Program (WHP)**

**WHP Quarterly Report**

**Q4 - 2021 (Oct-Dec)**
**Waterfowl Contaminant Conservation Project**

This fall, New York, New Jersey, Connecticut, and Pennsylvania collected waterfowl (mallards, wood ducks, black ducks, green-wing teal, and Canada geese) as part of a Multistate Conservation Grant research project to identify contaminants, such as Hg, PCBs, and PFAs, that might be present in these species most likely to be consumed by hunters. Present Dept. of Health consumption advisories may be outdated and based on other species.

This large-scale collection effort required randomly collected adult birds, which necessitated an online system where hunters could submit photos of wings for aging by agency waterfowl biologists. Tissues will be sent to laboratories in 2022 for chemical analysis. We appreciate all the samples that have been submitted for this important project!

**Moose with Brainworm, Liver Fluke, and Abscesses**

A 2½ year old female moose came to the WHU in November after being euthanized in the field due to emaciation and inability to stand. Upon examination, a healing fracture of the left hind leg and multiple abscesses, including a large one enveloping the spleen, were observed. The liver contained several abscesses and scar tissue consistent with liver fluke damage; evidence of fluke migration through other tissues, including the abdominal wall, was also found. A thorough brain dissection revealed one *Parelaphostrongylus tenuis* (deer brainworm).

Diagnostic testing identified *Trueperella pyogenes* from the spleen abscess; the moose was negative for CWD and EHD. Brainworm infection in moose is often fatal as it causes altered behavior resulting in reduced foraging, poor body condition, and predisposition to traumatic injury. *Giant liver fluke* (*Fascioloides magna*) infection is common in NY moose and can result in extensive liver damage, but in this case the damage may not have been severe enough to be a significant contributing factor in the condition of this moose.

---

**Keeping an Eye Out - Surveillance Reminders**

*High Path Avian Influenza detected in Canada, South & North Carolina; report respiratory & neurologic signs or unusual numbers of mortality in waterfowl or raptors.

*RHDV2 confirmed in domestic rabbits in Montgomery County; report wild rabbits with bloody faces or large numbers of mortality.

**Fact Sheets Library Growing**

We've added more disease guides to the CWHL Resource Library - check them out!

**Publications & Software and more**

The WHP team has two publications in press and seven new software apps on wildlife disease & management.
